Cagan hypothesis: rate × T_{max} ≈ const | 15 mammalian species, T_{max} from AnAge
VBLS with uniform scaling gives φ = −1, also in the sampled age windows; data give φ = -0.66, which the model does not explain
Hatched bars (left) and diamonds (centre): 4 species outside the ±50% band, see text

Data: Cagan et al. (2022) Nature 604:517-524; T_{max}: AnAge
